카드 요약 / 당시 확인 내용

University of Minnesota Extension's Field Notes discussion covered twospotted spider mite and soybean aphid pressure. Hot, dry weather strongly favors spider mites: plants stressed by heat and drought become better quality food, reproductive rates surge in the upper 80s to 90s Fahrenheit, and naturally occurring fungal pathogens that suppress mites are inhibited because they require temperatures below 85F and high humidity. Scouts should check field edges and tap leaves over white paper. Product choice matters, as miticides with ovicidal activity prevent rebound populations. Soybean aphid populations remain relatively low and scattered; the economic threshold is an average of 250 aphids per plant with 80% of plants infested and populations increasing. Pyrethroid resistance is widespread; research showed applying pyrethroids to resistant populations increased aphid counts tenfold relative to untreated checks because natural enemies were eliminated.
