카드 요약 / 당시 확인 내용

Researchers at the University of Nebraska - Lincoln, led by plant pathologist Dylan Mangel and working with CropVoice, are developing disease modeling and detection systems that identify soybean diseases before visible symptoms appear. The system uses genetically modified sentinel plants that fluoresce under UV light once infected, with UV cameras continuously monitoring trial plots and reporting findings in real time. The work focuses on white mold and other soybean diseases with an emphasis on timing fungicide applications more precisely. Mangel notes that current fungicide treatments are difficult to time accurately and that better prediction could help farmers time those fungicides better because they are not effective the whole season. The research remains at an early stage.
