카드 요약 / 당시 확인 내용

University of Minnesota Extension's August 24, 2026 late - season pest management update reported soybean aphid populations have been low but are increasing in some fields as temperatures cool. The economic threshold remains 250 aphids per plant (80% of plants infested, populations increasing), rising above 250 at the R6 full - seed stage; insecticide applications are typically unnecessary by late August as aphids migrate to buckthorn. Specialists warned that alternative treatments lack scientific support: claims that sugar applications make aphids 'diabetic' are unfounded since aphids redirect excess sugars as honeydew, elevated plant Brix shows no consistent correlation with reduced insect populations, and NDSU research found hydrogen peroxide produced no yield differences against white mold, unlike fungicides. The optimal white mold fungicide window (R2) has passed for 2026. For sudden death syndrome, effective seed treatments and resistant varieties are the prevention strategies; red crown rot, a newly emerging disease with reddish base discoloration, should be reported with photos for evaluation. Southern rust and tar spot remain at low levels in corn with minimal remaining yield risk.
