카드 요약 / 당시 확인 내용

A nine - year study of morning glories published in Evolution Letters (2026), led by University of Michigan researchers Sasha Bishop and Regina Baucom with John Stinchcombe of the University of Toronto, found that the plants' rate of adaptation dropped from approximately 76% to roughly 9% of the expected evolutionary pace when accounting for trait relationships. Selection increasingly favors larger flowers for pollinator attraction over earlier flowering that would aid climate adaptation. As pollinator populations decline due to pesticide use and habitat loss, plants face competing evolutionary pressures that constrain their ability to adapt to climate change. Although morning glory is a troublesome agricultural weed, its unpredictable evolutionary trajectory makes its future impact on farming uncertain. The research highlights a lag between theoretical rapid adaptation and observations in wild populations, many of which are declining or passing through genetic bottlenecks despite sufficient genetic diversity.
