CoBank's Knowledge Exchange division contends that elevated fertilizer prices reflect structural market shifts rather than temporary cycles, requiring growers to prepare for an extended period of elevated input costs. Global phosphate capacity/production forecasts are down 13% from pre-crisis levels (from nearly 69 million tons to under 60 million tons), and capacity additions will not fully offset losses before 2028 at the earliest. Three structural drivers: the Strait of Hormuz disruption removed critical sulfur supply, raising phosphoric acid production costs globally — ammonia and sulfur are the two biggest variable cost inputs for phosphate production and three of the world's 10 largest ammonia exporters are behind the Strait of Hormuz; Russia's sulfur export ban intensified competition among North African, Middle Eastern and Asian producers; and expected new facilities in Morocco and Saudi Arabia face timeline risks. Phosphate application cutbacks under way in fall 2026 could extend into 2027 and beyond, and CoBank cautioned that no substitute can fully replace conventional phosphate fertilizer at commercial scale, with precision nutrient management and soil testing offering limited mitigation.
