Nebraska Extension, in cooperation with industry partners, established test plot strips across the Nebraska Panhandle over more than four years evaluating a combination of indaziflam (Rejuvra) and imazapic (Plateau) for cheatgrass management. Native perennial grass biomass production was 2.5 times greater in treated areas than in untreated areas. Approximately 2.3 million acres, over 20% of the Nebraska Panhandle, face cheatgrass infestation, creating both forage production losses and wildfire hazards. Ranchers who implemented treatment observed increased native forage production and quality, resulting in higher weaning weights and improved cattle conditioning, and some producers expanded treated acreage after initial success on smaller plots. Extension educator Gary Stone recommends producers contact their local Natural Resources Conservation Service office for programs to offset invasive grass management costs and pursue grants particularly in fire - prone and post - fire areas.
