카드 요약 / 당시 확인 내용

Iowa State University Extension entomologists Ashley Dean and Erin Hodgson report western bean cutworm larvae causing injury in corn ears, with sightings in northwest and east central Iowa in 2026. The pest was historically problematic in the early 2000s but became rare after 2009. The caterpillar is smooth - skinned with a tan head featuring two dark rectangles behind it; mature larvae may appear gray or white with faint body striping, distinguishing them from the bumpier corn earworm. Larvae consume corn kernels and deposit frass, and unlike corn earworm multiple caterpillars may be present in a single ear and found anywhere on the ear, reducing grain quality and potentially affecting livestock feed safety. No in - season management is recommended once larvae enter ears. The Vip3A trait is the only transgenic trait that currently provides adequate suppression of western bean cutworm larvae, and growers should consult the Handy Bt Trait Table. Future management emphasizes scouting for egg masses and monitoring for mold on damaged ears.
