## 카드 요약 / 당시 확인 내용

Soybean cyst nematode (SCN) costs U.S. farmers approximately \$1.5 billion annually as the top yield - robbing soybean pest. PI 88788, the dominant resistance trait since the late 1980s, is losing effectiveness: Iowa State University data (2001 - 2023) shows SCN's ability to reproduce on PI 88788 increased 2% annually, with projections suggesting only 40% control by decade's end, causing roughly 9 bushel - per - acre losses. BASF's Nemasphere transgenic trait, launching in 2028, is the first new novel mode of action to combat SCN in more than 60 years, using a Cry14Ab - 1 protein fatal to nematodes, stacking with native resistant traits and Enlist E3 varieties, and expected to restore historical PI 88788 - level protection. Recommendations: test soil for SCN egg counts post - harvest, plant corn - on - corn when counts exceed 10,000 per half - cup of soil, rotate between PI 88788 and Peking traits annually, apply nematode - protectant seed treatments, and plant non - host crops.
