카드 요약 / 당시 확인 내용

Daniel Junior de Andrade, associate professor at Sao Paulo State University (UNESP) who coordinates the Laboratory of Acarology, explained on September 14, 2026 that mite control is becoming more challenging in Brazilian citrus groves. Primary pests are the citrus leprosis mite (*Brevipalpus yothersi*) and citrus rust mite (*Phyllocoptruta oleivora*), with spider mites (*Panonychus citri*, *Eutetranychus banksi*, *Tetranychus mexicanus*) and broad mite (*Polyphagotarsonemus latus*) as secondary pests. Recent cases of mite populations resistant to acaricides have emerged in some regions, complicating control. Higher - density plantings facilitate mite spread between plants while preventing acaricide penetration into inner canopy areas where mites shelter. Recommendations: sample at least 2% of plants per plot, intervene at a 3% infested fruit/branch action threshold, apply high - quality acaricides with varied modes of action, prioritize monitoring and timely decisions, and invest in alternative control research.
