University of Minnesota Extension published guidance on September 9, 2026 on seeding depth for winter rye and wheat amid drought, with 95% of Minnesota rated abnormally dry or worse. The standard seeding depth remains approximately 1.5 inches, balancing seed - to - soil contact with quick emergence, but the author recommends prioritizing seeding into moisture rather than sticking to the ideal depth and hoping for rain. Deeper seeding is viable in fall conditions: winter wheat up to 2.5 inches and winter rye 3 or more inches. Rye has the longest coleoptiles among small grains, followed by wheat, and warmer fall soil temperatures partially offset the longer emergence time of deep - seeded crops. Shallow seeding risks inadequate water uptake for germination and weak root development, while overly deep seeding delays emergence or prevents the coleoptile from reaching the surface, reducing stand establishment.
